The gentle sex? Assaults on women by women

P. BURDETT-SMITH & I. ADAMS

Accident and Emergency Department, St James’ University Hospital Trust, Beckett Street, Leeds

INTRODUCTION

Assaults on women have been the subject of many studies. (Gayford, 1979; Steinmetz, 1980; Knopp, 1984; Tanne, 1992). The concept of the 'battered wife' is widely accepted (Gayford, 1979). Organizations exist to offer help, counselling and places of safety to victims. However, recent Chief Constables' reports have highlighted an increase in the number of violent crimes perpetrated by women. Therefore, a study was instigated to assess all female victims of assault that attended the Accident and Emergency Department (A&E) of St James’ Hospital, to ascertain if violence to women, by women, is a significant problem.

METHODS

The Accident and Emergency Department of St James’ University Hospital covers the Eastern side of the city and it's suburbs, and receives approximately 78000 new patients per annum. It’s sister department – the General Infirmary, covers the Western side of the city, and receives similar numbers.

The study period ran from 22 October 1991 for 11 weeks, encompassing the Christmas and New Year holidays, until the 2nd of January. In addition to the usual history, i.e. the type of assault, weapon used and whether there was any loss of consciousness, all female victims of assault were asked the sex of their assailant, the number of assailants, whether they knew their attacker, and if they had been assaulted previously. The details of past assaults were not recorded and information on age, address, employment, time and date of attendance was collected from A&E records the following day.

167
The authors were mindful of the need not to distress these patients further, and additional questions were therefore kept to a minimum. The data was analysed by means of the chi squared test.

RESULTS

Over the 72 days of the study period, 124 female victims of assault were seen in the Department. This represents 0.18% of the 15328 attendances during the same period. Twelve records were incomplete because of reluctance on the victims part to disclose the information. Of the remaining 112, 27 (24%) were victims of assault by other women, two of which were attacked by both men and women but are included in this group.

Analysis

The results are summarized in Table 1.

Assaults by men on women

Female victims of male violence largely fall into the category of ‘battered wives’. Fothergill (1990) reported that ‘most women were assaulted at home, had been assaulted before and knew their assailant’. This was confirmed in our study. Over half reported previous assaults and 81% knew their attacker. Nearly always the

| Table 1. Assaults on women: analysis of data |
|-------------------------------|--------|--------|-------|
| Patient                       | Women  | Men    | Significance |
| Employed                      | 52 (14)| 38 (32)| n.s.        |
| Known to victim               | 30 (8) | 81 (69)| P < 0.0001  |

assailant was the boyfriend, husband, or ‘ex’. They were very much more likely to be attacked by just one man, (93%) and to be hit once.

There was a higher incidence of loss of consciousness in this group and victims were much more likely to require admission.

**Assaults by women on women**

When women attack women, there seems to be much more violent intent. In this group, over one-third (37%) were attacked by more than one assailant compared to just 7% in the male group. Very few (30%) know their attacker before the incident and there is a lower incidence of previous assaults. Over 80% were hit more than once and 63% kicked, compared to 60% and 29% respectively in the male group. Weapons were used equally by both groups with the stiletto heel on a shoe being common among women assailants. On average the patients in this group were younger and more likely to be employed.

**Outcome**

Assessment of the injuries inflicted reflects the different force used by the two sexes. The higher incidence of both X-rays and fractures in the female group is a reflection of the more violent intent and the frequency of multiple blows. Seven per cent of both groups required sutures and a similar number required follow-up. No victims of female violence were admitted, compared to six (7%) of those attacked by men. This suggests that although the number of injuries sustained by victims of female attack is higher, the severity of the injuries is less. This is supported by the higher incidence of loss of consciousness in the male group. The day, date and time of attendance was also recorded; (Figs 1 & 2).

Violence by women occurred mainly at the weekend, although there was a smaller peak midweek. (The figures apply from 1200 to 1200 h and thus include early morning and late evening on the same day.) In contrast, violence by men is much more evenly spread during the week with a less noticeable peak at weekends. This may represent delay in attending until the assailant is out of the house, but most victims of assault attend within a few hours of the attack.

Distribution by time is also much more even in the male group. Both groups attend the department mainly between 1200 and 0200 h (male 30 (35%), female 11

(41%). Of the subjects, 61% attended between 1900 and 0300 h. This is similar to the 63% reported by Driscoll (1988). There were no attendances by victims of female violence between 0300 and 1000 h and only four before 1800 h. In contrast, victims of male violence presented at any time during the day.

DISCUSSION

When the problem of assaults on women is addressed, most attention is focused on assaults by men. A recent North American report (Tanne, 1992) states that in 1990 'one-third of the women murdered in this country were killed by their husbands, ex-husbands or boyfriends. Each year approximately 626,000 violent victimizations of women are committed by men they know well.' This study confirms that male violence to women is a major problem, but showed that one in four assaults on women are inflicted by other women. On analysis, there are definite differences between the two groups. Arguments are a common precursor to violence in both groups and although a history of alcohol intake was not obtained specifically, most attendances occurred in the early hours of Saturday and Sunday nights. Many of the cases in the female group appear to be the 'jilted' partner taking revenge, although undoubtedly some are arguments that have escalated into violence.

Comparison with other studies is difficult as these collected data on all assaults. Different departments workload varies widely; assaults account for between 1.5% (Driscoll, 1988) and 3.4% (Hebedoe et al., 1985) of total attendances. Women comprise between 15% (8) and 28% (6) of victims in these studies. There are parallels between the female group in this study and previous studies of male on male violence (Driscoll, 1988; Shepherd, 1988; Hocking, 1989). In both there is an increase in violence at the weekends, alcohol is often involved and the attacks occur in clubs or pubs during the evening and night. It appears that in these cases, women are acting more like their male peers, and using violence as a means of settling
Assaults on women by women

differences. By contrast, female victims of male violence attend consistently throughout the week (Hebedoe, 1985) as was confirmed in our study.

No references in the literature to the problem of violent assaults by women on women could be found. Most studies concentrate on male to female violence in the context of 'spouse abuse'. There are reports of the reverse, i.e. 'husband abuse', by violent wives (Steinmetz, 1980), but to our knowledge this is the first report of violence by women on women.

CONCLUSION

Approximately one quarter of the victims in this study of assaults on women were assaulted by other women. It follows that not all female victims of assault are 'battered wives' and resolving differences by means of violence is not limited to men. This was a preliminary study with small numbers. A larger ongoing study is planned in which questions arising from the study will be addressed.
