Cardiopulmonary arrest in general wards: a retrospective study of referral patterns to an intensive care facility and their influence on outcome

S Premachandran, A D Redmond, R Liddle, J Mary Jones

Abstract

Objective—To analyse the effect on outcome of referral to specialist facilities after cardiopulmonary arrest in a general ward.

Methods—A retrospective analysis of resuscitation records of 743 patients in whom cardiopulmonary resuscitation was performed in a general ward between 1988 and 1992. After successful initial cardiopulmonary resuscitation, patients were identified as transferred to coronary care unit (CCU) or intensive care unit (ITU), or as staying in a general ward.

Main outcome measure—Survival to discharge home.

Results—There were 322 initial survivors, of whom 148 (20% of the overall total) survived to be discharged from hospital; 63% of those transferred to CCU and 48% of those transferred to ITU survived to discharge, compared with 28% of those who stayed on the ward (P < 0.001). Of those aged less than 65 years, 75% survived to discharge after transfer to CCU and 54% after transfer to ITU, compared with 44% of those who stayed on the ward (P = 0.023); the respective figures for those over 65 years were: CCU 25%, ITU 34%, ward 25% (P = 0.014). Only half of those aged more than 65 years were transferred to a specialist facility, compared with 90% of those aged less than 65.

Conclusions—Transfer to a specialist care facility after resuscitation from cardiopulmonary arrest has an influence on outcome. Age as an independent factor is not an appropriate criterion to use in deciding on transfer. The decision to arrange transfer must always be taken by the most experienced person available, and in line with peer reviewed guidelines.

Methods

We carried out a retrospective study of patients resuscitated from cardiopulmonary arrest in general wards in a large district general hospital with a regional cardiothoracic centre.

We examined the resuscitation record forms for the years 1988 to 1992. Cardiopulmonary arrest was defined as the sudden cessation of circulation or respiration, requiring initiation of cardiopulmonary resuscitation. For the purpose of this study we included only those cases of cardiopulmonary arrest that occurred in general wards. Cardiopulmonary arrest treated initially in the accident and emergency department, intensive care unit (ICU), or coronary care unit (CCU), and cardiopulmonary arrest in children were excluded from the study. Our aim was to analyse the referral patterns from “non-specialist” facilities to an intensive care environment.

It has been established practice at the study hospital for over 20 years for the senior doctor present at a cardiopulmonary arrest to complete a summary sheet immediately afterwards. All completed forms were collated by the hospital resuscitation committee. When the seal on the resuscitation box was broken it had to be sent to the pharmacy for restocking and a new form supplied. This ensured a complete set of records.

This provided information on the place of arrest, type of arrest, immediate outcome, and whether the patient stayed in the ward or was transferred to ICU or CCU for further care. Additional information on those who survived to discharge was obtained from hospital records and the hospital computer PAS system.

Sixty five years of age is widely used as a cut off point for critical care facilities after cardiopulmonary arrest. We therefore looked specifically at the influence of patient age on outcome following cardiopulmonary arrest in
Cardiopulmonary arrest in general wards

In general hospital, patients transferred to CCU or ICU were compared using the \( \chi^2 \) test.

Results

In the 5 year period (1988 to 1992), 743 patients underwent cardiopulmonary resuscitation in a general ward; 322 (43%) were initially successfully resuscitated. Of the 322 initial survivors, 148 (20% of the total group) survived to be discharged from hospital (fig 1).

Survival outcome differed significantly (\( P < 0.001 \)) between CCU, ICU, and the ward: 63% of those transferred to CCU survived to discharge from hospital compared with 48% of those transferred to ICU and 28% of those who stayed in the ward (fig 2).

Of the 322 immediate survivors, 153 (48%) were less than 65 years old, and 169 (52%) more than 65 years old. Considering both age groups separately, the survival outcome differed significantly between CCU, ICU, and the ward. Among those less than 65 years, 75% of those transferred to CCU survived to discharge home compared with 54% of those transferred to ICU and 44% of those who stayed in the ward (\( P = 0.023 \)) (figs 3 and 4).

The survival rates were lower among those aged more than 65 years. However, half the patients transferred to CCU survived to be discharged home compared with 34% of those transferred to ICU and 25% of those who stayed in the ward (\( P = 0.014 \)). Only half of those aged more than 65 years were transferred out of the ward to a specialist facility, in contrast to 90% of those aged less than 65 years of age, even though 52% of immediate survivors were more than 65 years of age (figs 5 and 6).

Discussion

In this retrospective study in a large district general hospital, outcome from cardiopulmonary arrest was related to postresuscitation care. The overall survival rate in our study compared favourably with the findings of other studies.

However, survival rates differed significantly between those who were transferred to CCU.
and ICU and those who stayed on the ward. Those who were transferred to CCU had the best chance of survival at all ages. This may represent patient selection as well as differences in clinical management (for example, better pain control, early detection and treatment of dysrhythmias). 6-8 This will be examined further.

Forty per cent of those who were resuscitated could not breathe spontaneously and were transferred to ICU for mechanical ventilation. Their survival rate was 48%. One third of those over 65 years age who required mechanical ventilation survived to discharge home. There were no cases where patients were electively ventilated after cardiopulmonary arrest. Treatment in an ICU after cardiopulmonary arrest does seem to have a place in postresuscitation care, even for those who initially cannot breathe. Those who remained in the ward had a survival rate of only 28%.

It is clear that patients were being selected into and out of specialist treatment areas in the early aftermath of a cardiopulmonary arrest. Age of the patients appeared to have influenced transfer of patients to an intensive care facility, and referral to a specialist facility did make a difference. A cut off point of 65 years would seem inappropriate for some patients, and the value of age alone as a criterion is doubtful. 5

All patients who were resuscitated from cardiopulmonary arrest should be considered for admission to an intensive care or coronary care unit, as the survival rate for those who remain in the general wards is significantly lower at all ages. A decision to keep the patient in a ward should be reviewed in the same way as a DNR (do not resuscitate) order and must therefore be taken at consultant level after discussion with the relatives or the patient, or both. 3, 9

Predicting who will benefit most from specialist and intensive care after cardiac arrest is difficult. The absence of a measurable blood pressure when measured with a cuff is very unreliable and will not identify accurately those with a poor prognosis. 10 Failure to breathe immediately, and even the age of the patient, cannot be relied upon to identify easily those most likely to benefit from intensive or other specialist facilities.

Anxieties about the use of intensive care facilities for postarrest patients may be unjustified, since half of the patients will live to be discharged home. The decision to use these expensive facilities can be difficult and often has to be balanced against the benefit to the patient.

There was obviously some selection of patients, but the point we wish to emphasise is that this was never laid down in any open policy. Junior doctors were making such decisions without reference to any agreed guidelines and on the spur of the moment. Possibly they did exclude patients with other serious medical conditions that would have prejudiced outcome on an intensive care facility, but this was never stated in the records. Detailed information about the medical status of the these groups would be too difficult to extract from the data available to us in this study. The results may not be explained entirely by selection, but given that failure to use such facilities has a significant effect on
Cardiopulmonary arrest in the postarrest period

More closely and evaluate criteria, it must be a decision that should be taken by a consultant. We recommend strongly that the use of intensive care facilities in the postarrest period should be monitored far more closely and recommendations developed. Our findings are to be followed up with a more detailed study to include information on the underlying disease and the nature of the cardiopulmonary arrest.

We are indebted to Wythenshawe Hospital resuscitation committee for their assistance and to the consultants for access to records of their patients, we thank Dr N H Brooks, consultant cardiologist, Dr K Shearer, hospital practitioner in cardiology, Wythenshawe Hospital, for their valuable comments.

ADVANCED LIFE SUPPORT GROUP

Major Incident Medical Management and Support Courses: to be held in various centres throughout the UK in 1997. This is a three day course in “life support style” designed to train health service personnel to provide an effective response at a major incident.

Fee £300.00

Advanced Paediatric Life Support Courses: to be held in various centres throughout the UK in 1997. This is a three day course designed to provide training which will enable doctors and nurses to deal efficiently with all paediatric emergencies. The course is modular and has sections on paediatric resuscitation, serious illness and serious injury.

Fee varies according to centre. Range £300.00 - £350.00.

Inquiries for both courses to:
