The best evidence topic report: a modified CAT for summarising the available evidence in emergency medicine

K Mackway-Jones, S D Carley, R J Morton, S Donnan

In order to achieve the optimal care for patients in the emergency department it is essential that their management is based upon the best available evidence. While the concept of evidence based medicine is widely accepted across many hospital and community specialties, emergency medicine has lagged behind in formalising the approach to evidence based practice.

One commonly used approach is that of the critically appraised topic (CAT).

This was designed to be a one page summary of the evidence related to a particular clinical question. This established method would appear to be a reasonable starting point for developing a clinically based approach to examining the evidence in emergency medicine. Unfortunately problems have been identified. CAT’s work best when based on papers that stand up to rigorous critical appraisal. In emergency medicine the evidence that does exist is frequently not of high quality, and consequently the critical appraisal process would tend to discard many papers because of either methodological flaws or poor design. The experience of the critical appraisal journal club was that an absolute requirement for high quality evidence meant

that large numbers of clinical questions in emergency medicine could not be answered at all. It became apparent during the searches that evidence of lower quality was available, and that this could be assimilated to give the best available answer at the present time.

This realisation that it was necessary to use the best available evidence led to the development of the best evidence topic report (BET) discussed below.

**Design**

BETs are constructed in four stages, based on the principles underlying all evidence based medicine. These stages are summarised in box 1 and are discussed below.

**Box 1**
- Asking the right question
- Searching for the evidence
- Appraising the evidence
- Summarising the evidence

**ASKING THE RIGHT QUESTIONS**

If a BET is to have real meaning to practising clinicians it is important that each topic selected is rooted in the practice of emergency medicine. In order to ensure that this is the case a clinical scenario is developed to illustrate the topic of interest. This scenario will be familiar to the person preparing the report, and will represent a real clinical problem in emergency medicine.

In order to ensure that the question is well defined and answerable a three part question is prepared from the clinical scenario. This process is well described as a tool for evidence based medicine. The three part question has the structure shown in box 2.

**Box 2**
- Patient characteristic
- Intervention(s) or defining question
- Relevant outcome(s)

It is vitally important to define the three part question well as this helps ensure that an appropriate search strategy can be formulated. An example of a general question of interest and a derived three part question are shown in box 3.

**SEARCHING FOR EVIDENCE**

In order to ensure that as much evidence as possible is included in the BET, it is essential that search strategies are sound and explicit. Two sources are explored in the construction of a BET. First the Medline database is searched using a strategy constructed as outlined below. Secondly the Best Evidence CD-ROM can be searched to see if there are any relevant systematic reviews.

**Medline**

There are three parts to the Medline search. First it is necessary to use search terms to produce a subset of the Medline database that contains all the papers relevant to the subject defined by the three part question. Second evidence based or methodological filters are applied if appropriate. Finally the titles and abstracts of the "hits" are scanned to see which papers are actually relevant to the question posed. Techniques for searching the Medline database have been reviewed recently.*

**The subject search**

In order to achieve the aims of the BET (finding and summarising the best evidence) it is important that the subject search has a high sensitivity (that is it has a high likelihood of retrieving all relevant items) so that important evidence is not overlooked. It may be necessary to use a number of different search strategies (that is use different search terms and combinations of terms) as well as using search terms that cover a slightly broader question. Greater sensitivity is achieved by using a combination of free text and text words together with medical subject headings (MeSH). A particularly useful feature enabling increased search sensitivity is the explosion command; this maps an individual MeSH term on to other related MeSH terms. Since some 50% of the articles

Applying filters

If a properly sensitive search carried out in a relevant area still yields a large number of hits then filters can be used. These are search strategies that have been designed to perform particular tasks such as finding randomised controlled trials or research overviews. A number of these are available in the public domain and have been published or can be found at appropriate web sites.

The vast majority of questions of interest to emergency physicians at the present time (and therefore those most likely to appear as BETs) involve either treatments (interventions) or diagnosis. An appropriate filter for intervention studies in the context of BETs is a maximally sensitive randomised controlled trial filter; one such is shown in table 1.

Diagnostic questions require a different approach since randomised controlled trials are not in general an appropriate method of investigation. In such cases an appropriate diagnostic evidence based medicine filter can be used. Diagnostic evidence filters and other evidence based filters appropriate to different types of questions (such as epidemiological or aetiological ones) are available from the Centre for Evidence Based Medicine and other appropriate sources.

Making the searches explicit meant that they can easily be repeated to update the BET at a later date.

Scanning titles and abstracts

Once the subject search has been completed and any necessary filters have been applied a number of papers will fulfil the search criteria. There is no guarantee that these will all be relevant to the question posed and a final scan of titles and, if there is any doubt, abstracts will be necessary. Ideally a maximum of 50 papers will be left for scanning in this way, but on some occasions more than this number will remain despite increasing the specificity of the search. It is better to have a higher number of papers to scan than to miss relevant papers by over refining the search.

At the end of the scanning process a number of papers will be discarded as “irrelevant to the question”. All the other papers remaining will need to be critically appraised. This process is described below.

The overall search strategy used in the construction of a BET is summarised in fig 1.

APPRASING THE EVIDENCE

Evidence based medicine is not about dismissing all evidence that has not been gained by randomised trials and meta-analyses. Some types of question are not best answered by these approaches and appropriate evidence needs to be found for these. Furthermore for many questions in emergency medicine there is no appropriate research that stands up to rigorous critical appraisal. BETs are designed to find the best evidence that exists to answer a particular question. If high level evidence does exist then the question posed can be answered with some certainty. If high level evidence does not exist then best evidence available can be

Table 2 Type and strength of evidence

Figure 2 Critical appraisal strategy.

summarised, and the failure to find good evidence can be used as a springboard for appropriate research.

The first critical appraisal filter to be applied is the methodological filter. The question underlying the methodological filter is: “what is the appropriate design of research to answer this question?”, and, if more than one approach is possible the second question is: “what is the relative merit of each of the possible methods?”

In the case of questions concerning interventions the hierarchy of evidence shown in table 2 is generally accepted and is used in constructing BETs. Although other hierarchies have been proposed the concepts underlying them all are the same.

The highest available level of evidence is used to construct the BET—thus level I evidence will be used if it exists; if there is no level I evidence then level II will be sought and so on.

Once papers containing the highest level of evidence available have been identified, they are critically appraised. The critical appraisal methods used are standard and have been published in a number of places. Key questions include methodological and analytical soundness.

After critical appraisal a paper may be found to be so flawed as to be unusable and will thus be discarded as of “insufficient quality for inclusion”. If a paper is not fatally flawed or if, despite being flawed, it represents the best evidence that is available it will be included in the BET. Comments about study weaknesses will be included in the last column of the table summarising the evidence.

The overall strategy for critical appraisal used in the construction of the BET is summarised in fig 2.

Summarising the evidence
In order to keep a record of appraised topics a summary of the evidence is made in the form of a BET. The first of these BETs appear in this month’s journal. The reports follow a standardised format. This includes the title, the clinical scenario, the derived three part question, the detailed search strategy, and the results of the search. The number of “hits” is followed by the number of papers which were not relevant to the question and the number which were of insufficient quality for inclusion (after critical appraisal). Those papers which are included in the BET are reported in table format. The table includes the author, date, and country of the research, the patients groups the study type (and the level of evidence), the outcomes that were investigated,
the key results for each outcome and the study weaknesses that were identified. A further analysis of the results of the best papers may be given if the results allow this. Free text comment about the search and its outcome is then given, followed by the clinical bottom line (the answer to the original question). The references of the relevant papers are given in full.

The template for the BET is shown in table 3. Each BET is attributed to a main author and also a subsidiary author who is responsible for checking the search strategy and outcome.

NEGATIVE BET REPORTS

It is foreseen that a significant number of topics will fail to produce any evidence to answer the clinical question posed. These “negative” BETs are indicative of areas for further research, and a list of the questions for which no answer at all can be found should be culminated alongside “positive” reports.

Discussion

BETs are an attempt to formalise evidence based practice in the emergency department. Their very name indicates the uncertain nature of much of the “evidence” in this area. The hope is that by basing BETs on real problems in emergency medicine, real questions will be answered with the best evidence available. This process is essential as real questions about patient care arise on a daily basis in the emergency department, yet there is rarely time to search for evidence at the time of a patient presentation. It is therefore essential to be proactive in the approach to evidence based practice. Emergency medicine is still a relatively young specialty and there is a paucity of high quality evidence for many aspects of practice, BETs will therefore not be confined to questions regarding new or novel practices and will examine the evidence for well established practices as well.

The BET does have its weaknesses. While it reports the best available evidence obtained through literature searching on Medline and other information resources, it does not examine unpublished literature in the way that systematic reviews do. It is unlikely that systematic reviews will become available for many of the more minor complaints that present to the emergency department for some time. Even if they did, as the BETs will show, it is unlikely that much of the evidence would pass the methodological filters used in systematic reviews.

BETs contain the best evidence that can be practically obtained by busy practising clinicians and should be used to inform best practice. They can be disseminated among members of journal clubs, training schemes, and can be published in peer reviewed journals or web sites. It is hoped that BETs will demonstrate both the strengths and the weaknesses of the evidence base on which the practice of emergency medicine is based.
