Acute myocardial infarction in patients with left bundle branch block

EDITOR.—We read with interest the paper about the electrocardiographic diagnosis of acute myocardial infarction (AMI) in patients with left bundle branch block (LBBB). It emphasises the difficulties many have had with electrocardiogram (ECG) interpretation in this situation and explains clearly how to use the criteria of Sgarbossa et al. It concludes that these criteria can be used to identify patients with LBBB and AMI.

It is essential that accident and emergency staff recognise this group of patients so that thrombolysis is delivered promptly. Shlipak et al. reviewed patients presenting with LBBB and an acutely diastolic murmur and assessed the usefulness of the Sgarbossa criteria. They found that these criteria had a sensitivity of 89% and a specificity of 100%. Although an ECG that satisfies the criteria is almost certainly indicative of AMI, most (90%) patients with AMI will not meet the criteria. If thrombolytics were to be withheld until the criteria were met, few patients in this high risk group would receive appropriate treatment.

Rather than relying on the Sgarbossa criteria, we feel it would be more appropriate to thrombolise all patients (except those with contraindications) who have a history suggestive of AMI and LBBB. This policy is supported by the data of Shlipak et al. It concludes that electrocardiographic ST segment elevation situated in an anatomic distribution; the presence of a new LBBB pattern represents another electrocardiographic criterion for such treatment. Shephard and Hardern suggest that all patients with LBBB pattern—presumably regardless of its chronology—and a history suggestive of AMI receive a thrombolytic agent. Such an approach is perhaps reasonable if the physician has a high suspicion of AMI and is comfortable initiating thrombolysis based solely on clinical information—in other words, an analysis of the patient's history and physical examination. Physicians, however, may be uncomfortable administering a thrombolytic agent under such circumstances; in fact, patients with electrocardiographic LBBB and AMI less often receive thrombolysis despite an increased risk of poor outcome and a proven benefit. The clinician must realise that of all patients with chest pain, electrocardiographic LBBB pattern without obvious infarction, and clinically presumed AMI, only a minority will actually be true AMI patients. Capnography should be considered mandatory in any patient requiring intubation, especially as an adjunct to cardiac arrest. The endotracheal tube must be replaced immediately in any patient not in cardiac arrest in whom ETOC is not detected. Endotracheal intubation continues to remain the gold standard for airway management for patients in cardiac arrest. The standard clinical signs widely used to confirm endotracheal intubation are again potentially unreliable and capnography is helpful. The use of a lit tracheal stylet (for example Trachlight Stylet and Tracheal Lightwand, Rusch Inc, Duluth, GA, USA), inserted through the endotracheal tube after intubation, can very simply provide indirect evidence of correct tracheal placement by transillumination of the soft tissues of the neck. This simple technique may help to reduce the tragedy of failure to recognise oesophageal intubation in critically ill patients.

The authors reply

We read with interest the comments of Shephard and Hardern concerning our article. In large part, we agree with their thoughts. In our report, we stressed several points, including (1) the confounding effect of LBBB pattern on the electrocardiographic diagnosis of AMI; (2) the “normal” or expected findings of LBBB and (3) national electrocardiographic strategies to assist in identifying the patient with a potential AMI. Several electrocardiographic strategies are available to the clinician to assist in this endeavour such as comparison with old ECGs, examination of serial ECGs, and a sound understanding of the anticipated ST segment changes resulting from LBBB. These strategies may be supplemented by the clinical decision rule developed by Sgarbossa et al.

Since our report was published, recent literature has suggested that the Sgarbossa et al clinical prediction rule is less useful than reported. The first such investigation, not noted by Shephard and Hardern, who applied the Sgarbossa et al criteria to patients with chest pain and an emergency department of a North American hospital, found much less promising results—a very low sensitivity coupled with poor interobserver reliability. And, as noted by Shephard and Hardern, a second study investigated the diagnostic and therapeutic impact of this criterion—none effectively distinguished the patients who had AMI from those patients with non-coronary diagnoses. The authors concluded that electrocardiographic criteria are poor predictors of AMI in LBBB situations and suggested that all patients suspected of AMI with LBBB should be considered for thrombolysis. As we stated, even if the clinician has a high suspicion of AMI and is comfortable initiating thrombolysis based solely on clinical information—in other words, an analysis of the patient's history and physical examination. Physicians, however, may be uncomfortable administering a thrombolytic agent under such circumstances; in fact, patients with electrocardiographic LBBB and AMI less often receive thrombolysis despite an increased risk of poor outcome and a proven benefit. The clinician must realise that of all patients with chest pain, electrocardiographic LBBB pattern without obvious infarction, and clinically presumed AMI, only a minority will actually be true AMI patients. Capnography should be considered mandatory in any patient requiring intubation, especially as an adjunct to cardiac arrest. The endotracheal tube must be replaced immediately in any patient not in cardiac arrest in whom ETOC is not detected. Endotracheal intubation continues to remain the gold standard for airway management for patients in cardiac arrest. The standard clinical signs widely used to confirm endotracheal intubation are again potentially unreliable and capnography is helpful. The use of a lit tracheal stylet (for example Trachlight Stylet and Tracheal Lightwand, Rusch Inc, Duluth, GA, USA), inserted through the endotracheal tube after intubation, can very simply provide indirect evidence of correct tracheal placement by transillumination of the soft tissues of the neck. This simple technique may help to reduce the tragedy of failure to recognise oesophageal intubation in critically ill patients.

Anaesthetic training for specialist registrars in accident and emergency

Editor,—Accident and emergency (A&E) trainees are required to spend a minimum of three months on secondment to anaesthetics and the intensive care unit (ICU) if they have not already obtained adequate anaesthetic/ICU experience before entering the specialty. The depth and breadth of experience varies widely. Sometimes, the trainee is purely supernumerary and gains little experience other than placing laryngeal masks and endotracheal tubes. We have each been fortunate enough to spend six months as trainee senior house officer (SHO) anaesthetists as part of our rotations. We feel that this offers considerable benefit to our training as A&E specialists and recommend it to other A&E trainees.

Anaesthetics is unlike any other clinical specialty. It is impossible to start as the sole “on call” anaesthetic SHO on the first day. Hospital varics, but most train new SHOs over three months before allowing them onto the on call rota. In our six month secondments we participated in the on call rota and have benefited from the responsibility of acute decision making. We have become increasingly competent in preanaesthetic assessment, sedation, pain management (including regional anaesthesia), and the induction, maintenance, and recovery phases of a general anaesthesia. We have performed rapid sequence induction independently. Our improved confidence in the management of the airway has to be good for patient care, especially as we often provide support to our colleagues in the ICU. We feel that this experience of acute decision making is necessary to provide the basis required to become independent anaesthetists.”

The change from “finished consultant emergency” to “spells” to so-called “stamper” could lose our departments funding for the care of patients awaiting admission in A&E departments and not formally under our care. The pilot sites are selected sites and the Casemix Office to deliver this refinement of our casemix measure. We owe them a debt of gratitude, especially when several of the sites will also be modernising their departments at the same time.

Prospective survey to verify the Ottawa ankle rules

Editor,—In their study to verify the Ottawa ankle rules Perry et al point out “the potential dangers of rigid adherence to decision rules”.

The study discovered that four malleolar fractures would have been missed had the guidelines (per the Ottawa ankle rules) been applied—that is, these patients would not have had radiography.

The data from the study were derived from the emergency department ankle “stamper”, which comprises 12 parameters. Of these they selected four: age, posterior malleolar tenderness (which malleolus was not specified), inability to weight bear immediately, and inability to weight bear in the emergency department. This information was deemed adequate to meet the study’s requirements.

However, age is a relevant eligibility criterion for application of the rules—it does not impact on decision making regarding radiography thereafter. Secondly, the failure to specify which malleolus was tender detracts from attempts at verification—the rules specify both malleoli must be assessed. Moreover, the study (and the stamper) ignores the second part of the ankle rules entirely—that is, navicular zone and fifth metatarsal zone tenderness.

5 Reference projects will look at the potential of the national triage scale (NTS) and details of how long a patient stays in the department, to see if they provide a further reduction in variance and can be easily collected to drive our HRG.

6 Work to date of this refinement project anticipates making recommendations to seek changes in the minimum dataset to include the NTS triage groupings, a separate investigation code for more expensive radiological investigations, such as intravenous urography, and a treatment code to identify patients receiving thrombolytic treatment.

7 The change from “finished consultant episodes” to so-called “spells” could lose our departments funding for the care of patients awaiting admission in A&E departments and not formally under our care. The pilot sites are selected sites and the Casemix Office to deliver this refinement of our casemix measure. We owe them a debt of gratitude, especially when several of the sites will also be modernising their departments at the same time.

8 Editors of the study acknowledged that the burden of these patients place on our departments...
In view of the authors’ decision to apply only part of the Ottawa ankle rules, and the disregard for one of the malleoli, it seems inappropriate to conclude that “although useful, decision rules should be used with care and cannot replace clinical judgment and experience”.

BRENDAN McCANN

Dr Perry replies

Thank you very much for giving me the opportunity to reply to Dr McCann’s letter. I disagree with Dr McCann’s comments about age. The Ottawa ankle rules clearly state that plain radiography is indicated if the patient is aged 55 years or greater.

The authors accept that our stamper did not specify which malleolus had been examined and may, theoretically, have resulted in some patients being recorded as “Ottawa negative” inappropriately. However, it is never the intention to study the form of presentation makes a fast track service for this vulnerable group of patients.

Fast tracking patients with a proximal femoral fracture—more than a broken bone

EDITOR.—In 1996 we described a system of fast tracking admission of patients with a proximal femoral fracture to the ward where definitive management could begin. This system had benefits for all those involved, not least the patients who are mostly elderly women at risk of developing pressure sores.

Since we published the paper a number of changes have occurred at our hospital which reflect changes occurring in many hospitals in the NHS: the number of acute orthopaedic beds on the hospital site fell from 75 to 60; the number of acute admissions, particularly medical, has continued to rise; and improved resources and initiatives for managing emergency admissions have suffered at the expense of initiatives for reducing waiting lists.

In January 1999 we reviewed the length of stay in the accident and emergency (A&E) department for 25 consecutive patients over 65 years of age who were admitted with a proximal femoral fracture and compared them with figures for patients who were fast tracked in our original paper (fig 1). Although the 1995 figures were for patients who were fast tracked, the mean time for patients who could not be admitted because of the unavailability of an orthopaedic bed had still been only 4 hours and 8 minutes. The average length of stay has risen sharply with 40% of patients now staying in the A&E department for more than seven hours.

This apparent breakdown of a quality improvement initiative is an example of how emergency patients are suffering because of reduced numbers of acute hospital beds and a reduction in resources available for acute cases. In 1998 there were 812 cases of proximal femoral fracture over the age of 65 years admitted to our hospital. We advocate the availability of three dedicated beds each day for the management of patients with a proximal femoral fracture. The predictability of numbers and almost uniformity of presentation makes a fast track system for this type of injury eminently suitable. It is important, however, that hospital management work alongside clinicians in providing the necessary resources to develop a fast track service for this vulnerable group of patients.

Fast tracking patients with a proximal femoral fracture

CS incapacitant spray

EDITOR.—In 1996, CS incapacitant spray was sanctioned for the use of police forces in England and Wales. As its use increases the demands on accident and emergency departments from individuals who have been exposed to this will also increase. Some of the points in Worthington and Nee’s review are worth clarifying.

The experimental work into the safety of CS was performed on pyrotechnically generated CS. The spray used by the police produces a mist that contains CS as a supersaturated solution or as a fine powder. The solution in the spray is a 5% w/v solution dissolved in methyl isobutyl ketone (MIBK).

The American forces use a 1% solution.

Pulmonary oedema after CS exposure has been reported, but only in conditions where the victim has been unable to escape, and is trapped in a confined area—that is, on exposure to very high concentrations. Equally burns to skin occur in specific conditions: high temperature, humidity, high concentrations, and prolonged exposure.

As mentioned at the outset these experiments were conducted on CS produced by a different method and it is difficult to extrapolate the results to a totally different type of exposure. The solvent, MIBK, has a low volatility, therefore in areas protected from air currents (behind ears, in skinfolds, under clothing bands, etc) it may not evaporate, prolonging the contact in warm moist areas. MIBK, itself, also has the potential to cause inflammation, dermatitis, and burns to the skin.

Although the standard advice regarding management of CS exposure is to remove the subject from the source and allow a flow of fresh air over the affected parts, if symptoms are persistent irrigation and bathing are required, as skin irritation may not be caused by CS but by MIBK.

R D SOUTHWARD
Specialist Registrar in Accident and Emergency,
Sunderland Royal Hospital,
Keel Road,
Sunderland SR4 7TP

The authors reply

We thank Mr Southward for his comments on our paper. Comprehensive data on CS incapacitant spray are lacking, particularly with regard to the more concentrated solution in use by UK police forces.

Mr Southward reminds us that serious effects are more likely with excessive or prolonged exposure and are generally mitigated by the victim being removed to a well ventilated area. We recommended irrigation of the eyes for severe symptoms as well as suggesting some general measures for decontamination and the treatment of cardiorespiratory complications.

Mr Southward recommends that particular attention be given to areas of the body where air flow may not occur and we are grateful to him for providing this additional advice.

Figure 1 Length of stay in the A&E department for patients admitted with a proximal femoral fracture.
A rare cause of acute confusional state

Editor,—A 42 year old man presented after attempts to eradicate a wasps’ nest in his attic with Rentokil wasp killer spray containing carbaryl 5%. The area was enclosed without windows. He was aware of the potential for toxicity and wore a cotton homemade mask. He sustained two wasp stings as he sprayed and his wife reported him staggering into the living room about 20 minutes later. Shortly after this he lost consciousness.

On arrival he was acutely confused and combative. Both conjunctiva were injected. He was haemodynamically stable with oxygen saturations >95%. He was diaphoretic and wore a cotton homemade mask. He had been in contact with Rentokil wasp killer spray containing carbaryl 5%. The area was enclosed without windows. He was aware of the potential for toxicity and wore a cotton homemade mask. He sustained two wasp stings as he sprayed and his wife reported him staggering into the living room about 20 minutes later. Shortly after this he lost consciousness.

Installation of the software is simple. Within minutes the novice is introduced to the basic physics and practicalities of sonographic imaging. Each organ of the abdominal cavity is anatomically orientated via a 3D animated model or coronal computed tomographic videographic image, relevant acoustic windows and shadows are highlighted, and normal ultrasonic images are emphasised. Representative images of common abnormalities, such as organomegaly, cysts, tumours, ascites and calculi, are presented via real time video images and multiple still images. Practical skills such as frame selection and organ measurement are emphasised and assessed. Cross reference icons allow for rapid updates of unfamiliar terms and principles, both within the text or via the world wide web.

This CD-ROM costs US$175 for individual use and US$495 for institutional use (plus shipping costs outside the US). While the educational content and the graphical quality are impressive, this CD-ROM requires more emergent case studies, particularly traumatic cases, for its to be of clinical and financial value in an accident and emergency department.

THOMAS CARRIGAN
Specialist Registrar in Accident and Emergency, Leeds

Oxford Clinical Mentor CD-ROM or floppy disk. Single user version, network versions available. Oxford University Press. (Available from Healthwork Ltd, 30–38 Dock Street, Leeds LS10 1FJ; tel: 0113 234 6624, fax: 0113 242 7782, e-mail: sales@d-access.demon.co.uk; the Oxford Clinical Mentor Plus is the new updated and expanded edition of the Oxford Clinical Mentor and costs £150 plus VAT.)

Increasingly well known medical texts are being republished as software for use on computers. These may have advantages over print and paper for the computer literate user particularly for the facility to search text rapidly.

The Oxford Clinical Mentor is described as an “electronic medical knowledge support system”. More precisely it consists of the texts of the Oxford Handbook of Clinical Medicine and the Oxford Handbook of Clinical Specialties presented for use on a personal computer. Additionally the Oxford Handbook of Clinical Rarities is included, which is not available as a book. An IBM compatible computer with a minimum specification of a 486 DX-66 with 8 MB RAM and 30 MB hard disc space is required. The software runs under Windows 3.1 (or higher) or Windows 95. The publishers state that it is designed “for use in GP’s surgeries, hospital casualty departments and by medical students everywhere”. The main search window allows rapid access to the information required but takes a little time to master. The text provided is of high quality and will be familiar to many who have used the books. The emphasis is on general medicine and though most other areas of medicine are covered, it could not be accepted as the comprehensive text for doctors working in accident and emergency (A&E) departments. There is extensive cross referencing that is accessed by electronic jumps and references for further reading. There is a temptation to browse through the different sections of the programme, which might prove a distraction for junior colleagues.

Although the Oxford Clinical Mentor is an innovative way of providing access to medical information its clinical content is more suitable for use in general practice than A&E. A similar system more orientated to the clinical problems of A&E medicine would be a welcome addition to a department’s resources. While the Oxford Clinical Handbooks are a valued part of most departmental libraries, I would not recommend the purchase of this electronic version for use on A&E computer systems.

GRAHAM JOHNSON
Consultant in Accident and Emergency Medicine, Leeds

CD-ROM REVIEWS

Abdominal Ultrasound: Principles and Techniques. CD-ROM written by Mark Deutchman, Associate Professor of Family Medicine, University of Colorado, Denver. Published by SilverPlatter Education Inc, Newton, Massachusetts, 1997. ISBN 1-57276-031-1. Hardware requirements: Multimedia PC with Microsoft Windows (8 MB RAM) or Windows 95 (16 MB RAM) or Macintosh (System 7.0 or later with 8 MB RAM). Details available from: SilverPlatter Education Inc 246 Walnut Street, Suite 302, Newton, MA 02460-1639, USA (tel: +1 800 521 0574/fax +1 617 244 0284).

The trend towards emergency abdominal ultrasound is filtering across the Atlantic. Observational studies have been made to study the impact and effectiveness of such imaging in the emergency department. This CD-ROM therefore seems appropriate for the accelerated learning of essential abdominal ultrasound principles and techniques.
