Best evidence topic reports (BETs) summarise the evidence pertaining to particular clinical questions. They are not systematic reviews, but rather contain the best (highest level) evidence that can be practically obtained by busy practicing clinicians. The search strategies used to find the best evidence are reported in detail in order to allow clinicians to update searches whenever necessary. The BETs published below were first reported at the Critical Appraisal Journal Club at the Manchester Royal Infirmary or placed on the BestBETs web site. Each BET has been constructed in the four stages that have been described elsewhere. The BETs shown here together with those published previously and those currently under construction can be seen at http://www.bestbets.org Eight BETs are included in this issue of the journal.

### Swimmers view or supine oblique views to visualise the cervicothoracic junction

**Report by N. Nasreen Contractor, Specialist Registrar**

**Checked by Martin Thomas, Specialist Registrar**

**Abstract**

A short cut review was carried out to establish whether swimmer’s views were better than superior oblique views at visualising the C7/T1 junction. Eleven papers were found using the reported searches of which one presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results, and study weaknesses of this best paper are tabulated. A clinical bottom line is stated.

**Clinical scenario**

A 36 year old man is brought to the emergency department after a road traffic accident. He complains of neck pain. A “pulled” lateral is taken, but fails to show the C7/T1 junction. You wonder whether a pair of supine oblique views or a swimmer’s view would be best to visualise this region.

**Three part question**

In a [trauma patient in whom standard lateral views of the cervical spine are inadequate] is a [swimmer’s view better than supine oblique views] at [visualising the C7/T1 junction]?

**Search strategy**

Medline 1966–07/02 using the OVID interface. [supine oblique.mp OR trauma oblique.mp OR swimmers view.mp OR twinig.mp] AND [exp X-Rays OR x-ray$.mp OR radiograph.mp OR exp radiography OR radiography.mp] AND [exp cervical vertebrae OR cervical spine.mp OR exp neck injuries OR neck injury.$mp OR cervicothoracic junction.mp.] LIMIT to human AND English.

**Search outcome**

Altogether 11 papers were found of which only one was relevant to the original question (see table 1).

### Table 1

<tbody>
<tr>
<td>Ireland AJ et al, 1998, UK</td>
<td>427 consecutive patients who attended with acute trauma requiring cervical spine radiographs. 60 patients required additional supine oblique views.</td>
<td>Two phase prospective study</td>
<td>Able to visualise the vertebral bodies and posterior elements of the cervicothoracic junction</td>
<td>37% of the swimmers group and 38% of the supine oblique group were judged satisfactory. When vertebral bodies not shown adequately, 70% of supine obliques and 37% swimmers showed posterior elements adequately</td>
<td>9 patients from supine oblique group lost, therefore not included in calculations</td>
</tr>
</tbody>
</table>
Comments
While there are numerous articles expressing personal views, there is only this one paper that attempts to answer the question. This paper showed no difference in visualising the vertebral bodies of C7/T1 junction between swimmers or supine obliques, but supine obliques did visualise the posterior elements better. But 9 of 62 of supine oblique data were lost, which could have swayed the results either way. Therefore more research is needed in this area.

> CLINICAL BOTTOM LINE
Local advice should be followed.

Computed tomography and the exclusion of upper cervical spine injury in trauma patients with altered mental state

Report by Martin Thomas, Specialist Registrar
Checked by Stewart Teece, Clinical Research Fellow

Abstract
A short cut review was carried out to establish whether CT scans of the upper cervical spine are necessary in trauma patients with altered mental status and normal plain radiographs. A total of 572 papers were found using the reported search, of which six presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results, and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.

Clinical scenario
A 20 year old man is brought into the emergency department having been hit by a high speed vehicle while crossing the road. He has a large haematoma to the head and is confused and combative. Plain radiographs of his cervical spine are normal, as are radiographs of his chest and pelvis. You request a CT brain scan and a CT of his upper cervical spine, as you have heard that plain radiographs can miss injuries in this area. The radiologist does not agree that this is indicated as the plain radiographs of the cervical spine appear normal. You wonder if there is any evidence to support your request.

Three part question
In [trauma patients with altered mental status] is [plain radiography as good as CT] at [diagnosing significant upper cervical spine injuries]?

Search outcome
Altogether 572 papers were found of which 566 were irrelevant or of insufficient quality for inclusion. The remaining six papers are shown in table 2.

Comment(s)
The results of most of the studies outlined above indicate that in high risk patients with reduced level of consciousness there is an incidence of upper cervical spine injury between 5.2% and 13.9% (with the patients in the study by Berne et al having an incidence of 35%). The sensitivity of plain radiographs has usually been found to be between 39% and 61%. If the incidence of cervical spine injury is estimated as 8%, and the sensitivity of plain films taken to be 50%, this means that 4%, or 1 in 25, of polytrauma patients with a reduced level of consciousness will have an upper cervical spine injury not evident on plain radiographs. The missed spinal injuries included unstable fractures in all studies where stability was considered. It should be noted that not all studies limited themselves to the upper cervical spine, though the majority of missed injuries occurred either here or in the C7/T1 region, where this could not be adequately visualised on plain radiographs. Further studies involving helical CT scanning of the entire cervical spine are planned.

Possible drawbacks of routine CT imaging of the upper cervical spine include adverse events occurring as a result of spending longer periods in the CT scanner. Such events were not specifically sought in any of the studies described. Spiral CT scanners, with faster scanning times, should minimise this risk. In addition, CT scans cannot be used to reliably exclude ligamentous injuries—other imaging modalities are required for this.

Clinical bottom line
The upper cervical spine should be scanned during CT scanning of the head in the polytraumatised patient with reduced level of consciousness.

Antibiotics in compound depressed skull fractures
Report by Baha Ali, Senior Clinical Fellow
Checked by Angaj Ghosh, Senior Clinical Fellow

Abstract
A short cut review was carried out to establish whether antibiotics reduce the incidence of meningitis in patients with compound depressed skull fracture. Altogether 198 papers were found using the reported search, of which one presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results and study weaknesses of this best paper are tabulated. A clinical bottom line is stated.

Clinical scenario
A 23 year old man attends the emergency department having been assaulted outside a nightclub with a hammer. He has sustained an isolated head injury with no loss of consciousness and is fully alert and oriented. He has a compound depressed left parietal skull fracture (confirm and defined by CT scan). No surgical intervention is considered. You wonder whether the administration of antibiotics will reduce the chance of meningitis developing.

Three part question
In [an adult with compound depressed skull fracture] does [the administration of antibiotics] reduce [the incidence of meningitis]?

Search strategy
Medline 1996–07/02 using the OVID interface. [(exp skull fractures OR skull fracture$) OR ((exp fractures, open OR compound fracture$) OR depressed fracture$) AND (exp skull OR skull$ OR cranium$ OR calvarium$) AND (exp antibiotics OR antibiotic$)] AND (exp diagnosis OR exp pathology OR specificity.mp) OR exp tomography, x-ray computed OR computed tomography.mp OR exp x-rays OR X-ray$) LIMIT to human AND English.
Antibiotics in patients with isolated chest trauma requiring chest drains

Report by John Butler, Specialist Registrar
Checked by Ian Sammy, Consultant, and Joel Desmond, Research Fellow

Abstract
A short cut review was carried out to establish whether the administration of antibiotics reduces the incidence of intrathoracic infection in patients who have had a chest drain inserted after trauma. Altogether 321 papers were found using the reported search, of which two presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results, and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.

Clinical scenario
A 25 year old man is stabbed in the chest during a pub brawl. He sustains an isolated chest injury that requires a tube thoracostomy. You wonder whether the administration of prophylactic antibiotics will reduce the incidence of intrathoracic infection in this patient.

Three part question
In [patients suffering isolated penetrating chest injuries which require tube thoracostomy] does [the administration of prophylactic antibiotics] reduce [the incidence of intrathoracic infection]?

Search strategy
Medline 1966 to 8/02 using the OVID interface. ((exp thoracic injuries OR chest injury.mp) OR exp Chest tubes OR exp Thoracostomy OR chest drain.mp OR thoracostomy.mp) AND (exp antibiotic prophylaxis OR antibiotic prophylaxis.mp OR exp antibiotics OR antibiotics.mp OR prophylactic antibiotics.mp) LIMIT to human AND English.

Search outcome
Altogether 321 papers were found, of which 308 were irrelevant. One paper was a systematic review of 11 other relevant papers up to 1997 that were also found on our search. Only one other relevant paper was found after this date. Therefore the systematic review and the remaining paper are included in table 4.

Comment(s)
The EAST Practice Management Group have recently performed an excellent quality systematic review on this subject that included all other studies except Gonzalez et al. They give figures that show that the number needed to treat with antibiotics to prevent an intrathoracic infection is six. They caution that the available studies are small and these studies look at chest drains inserted under differing clinical situations and by differing grades of clinicians.

Table 4
Lignocaine premedication before rapid sequence induction in head injuries

Report by John Butler, Specialist Registrar
Checked by Rupert Jackson, Specialist Registrar

Abstract
A short cut review was carried out to establish whether pretreatment with lignocaine (lidocaine) reduces the rise in intracranial pressure associated with intubation of head injured patients. Altogether 85 papers were found using the reported search, of which three presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results, and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.

Clinical scenario
A patient attends the emergency department having sustained a blunt head injury. On examination they have clinical signs of a blunt head injury. On examination they have clinical signs of a blunt head injury. You wonder whether the pretreatment with lignocaine will attenuate the rise in intracranial pressure from the rapid sequence intubation.

Three part question
In [head injured patients with signs of raised intracranial pressure] who need [RSI and ventilation] is [pretreatment with lignocaine better than placebo] at [attenuating the rise in intracranial pressure associated with RSI]?

Ultrasound or computed tomography in paediatric blunt abdominal trauma

Report by Ross Murphy, Senior Clinical Fellow
Checked by Angaj Ghosh, Senior Clinical Fellow

Abstract
A short cut review was carried out to establish whether computed tomography is superior to ultrasonography at identifying intra-abdominal injury in children. Altogether 123 papers were found using the reported search, of which six presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results, and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.
Clinical scenario
A 6 year old boy presents to the emergency department after falling out of a fast moving car. He is extremely distressed and appears to have sustained multiple injuries including a large laceration to his head, bruising and deformity to both forearms and his left lower leg. After initial assessment and stabilisation you decide to paralyse, intubate, and ventilate him before performing a head CT. However you are also concerned about the possibility of an intra-abdominal injury. You wonder whether an ultrasound or CT would be better at identifying this.

Three part question
In [a paediatric patient with blunt abdominal trauma] is [an ultrasound scan better at identifying intra-abdominal injury] than [a CT scan]?

Search strategy

</tbody>
</table>

Search outcome
Altogether 123 papers were found, of which 117 were irrelevant or of insufficient quality. The remaining six papers are shown in table 6.

Comment(s)
The studies do seem to indicate that CT is better than ultrasound at identifying intra-abdominal injury in children. However, as it is impossible to confirm most of the injuries identified on imaging, it is also difficult to compare the two imaging techniques with a definite gold standard.

This also needs to be considered in the light of the clinical scenarios encountered by emergency physicians. Because of the need for transport and the time it takes to perform CT, children with blunt abdominal trauma need to be stable and have no other injuries requiring urgent treatment. Most will also require sedation. Ultrasound can be performed in the resuscitation room, is much quicker, and is much less distressing to a terrified child.

► CLINICAL BOTTOM LINE
CT is better than ultrasound at identifying intra-abdominal injury in children.

Routine use of antibiotic ointment and wound healing

Report by A Van Zyl, D Abbott, D Andrews, P Reaves, Senior House Officers
Checked by Hamish Simpson, Consultant

Abstract
A short cut review was carried out to establish whether topical antibiotics improved the outcome of simple wounds. Altogether 71 papers were found using the reported search, of which one presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results, and study weaknesses of this best paper are tabulated. A clinical bottom line is stated.

Clinical scenario
A 26 year old man attends the emergency department with a simple laceration requiring suturing. You wonder whether application of a topical antibiotic ointment will promote healing and reduce incidence of infection.

Three part question
In [adults with non-contaminated lacerations] does [the application of topical antibiotics] reduce [the incidence of secondary infection, the length of time dressings are required and achieve a better cosmetic result]?

Search strategy

Search outcome
Altogether 71 papers were found of which 70 were irrelevant or of insufficient quality for inclusion. The remaining paper is shown in table 7.

Comment(s)
Although this study suggests that antibiotic ointment reduces incidence of infection there are a number of reasons at the moment why we would be reluctant to change current clinical practice. The intensive wound care used in the study may not mirror our own practice. Long term results and patients own assessment of outcome may be better indicators of the benefit of topical antibiotics, than the short-term effects measured in this trial.

Clinical bottom line
There is not enough evidence here to change current practice. A large multicentre study is indicated to provide more relevant answers.

Factor VIIa for intractable blood loss in trauma

Report by Jon Argall, Senior Clinical Fellow
Checked by Stewart Teece, Clinical Research Fellow

Abstract
A short cut review was carried out to establish whether factor VIIa is indicated in patients suffering intractable blood loss after trauma. Altogether 39 papers were found using the reported search, of which two presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results, and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.

Clinical scenario
A 29 year old man is brought into the resuscitation area having jumped out of a fourth floor window. He has abdominal and pelvic injuries but no chest, head, or limb injuries. He is bleeding intractably and the orthopaedic team and surgical team cannot agree on a plan of management. You suggest that operative management is required, but they would like to perform a CT scan before theatre to determine who will lead the surgery. Exasperated you wonder whether factor VIIa would help to stabilise the patient and reduce his requirement for transfusion.

Three part question
In [trauma patients with major blood loss and intractable bleeding requiring massive transfusion] does [recombinant factor VIIa] reduce [morbidity and mortality]?

Search strategy

Comment(s)
More studies are needed.

► CLINICAL BOTTOM LINE
Factor VIIa may have a role as a temporising adjunct to surgical haemostasis. Further research is needed.
