Oxygen therapy in acute stroke

Report by Katherine Potier de la Morandiere, Specialist Registrar
Checked by Darren Walter, Consultant

Abstract

A short cut review was carried out to establish whether supplemental oxygen reduces long term disability and mortality in patients attending the emergency department with stroke who do not require resuscitation. Altogether 18 papers were found using the reported search, of which one presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results and study weaknesses of this best paper are tabulated. A clinical bottom line is stated.

Clinical scenario

A 73 year old woman presents to the emergency department with a six hour history of left sided hemiparesis. She has a past history of hypertension. On examination she is GCS 15 with a dense left hemiparesis and her basic observations are stable. You wonder whether the use of supplemental oxygen in the acute stage is needed and will have any effect on long term prognosis.

Three part question

In a [patient presenting to the emergency department with a stroke who does not need resuscitative measures] is [supplemental oxygen better than no oxygen] at [reducing long term disability and mortality]?

Search strategy

Search outcome

Altogether 18 papers were found of which one directly addressed the three part question (table 1).

Comment(s)

This large, well conducted study shows no statistically significant difference between the two groups. It shows there is no benefit to giving oxygen routinely to stroke patients, and suggests if given to non-hypoxic patients with mild to moderate strokes may increase mortality. The results for severe stroke patients were inconclusive.

The authors hypothesise (based on a small number of animal studies) that this may be attributable to oxygen free radicals.

Report by Jonathan Costello, Specialist Registrar
Reported by Jonathan Costello, Specialist Registrar
Checked by Kerstin Hogg, Clinical Research Fellow
Abstract
A short cut review was carried out to establish whether VQ scanning has better utility than CT in investigating possible pulmonary embolus in patients with chronic respiratory disease. A total of 239 papers were found using the reported search, of which one presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results and study weaknesses of this best paper are tabulated. A clinical bottom line is stated.

<td>Impairment at seven months (Scandinavian Stroke Scale) Survival at one year</td>
<td>No statistical significant difference (p = 0.3) in survival rates. One year survival greater in control group (72.9% v 68.8%)</td>
<td>Effects of being treated in a stroke unit</td>
</tr>
</tbody>
</table>

Search outcome
Altogether 239 were papers found of which 238 did not address the exact question. One paper was of relevance (table 2).

Comment(s)
Surprisingly few comparative studies. Ultimately small number studied in the study in question. Rigid definition of study population and reporter bias pose difficulties in such a study group. Diagnostic utility of V-Q questionable because of high proportion of inconclusive results—resource and economic factors are thus of relevance.

> CLINICAL BOTTOM LINE
There is not enough evidence to support V-Q Scintigraphy as the initial investigation of choice in COPD patients.

Combining clinical probability and ventilation-perfusion scan for diagnosis of pulmonary embolism

Kerstin Hogg, Clinical Research Fellow
Ged Brown, Specialist Registrar
Abstract
A short cut review was carried out to establish whether clinical probability estimates improve the utility of VQ scan results in patients being investigated for possible pulmonary embolus. Altogether 387 papers were found using the reported search, of which six presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results and study weaknesses of this best paper are tabulated. A clinical bottom line is stated.

outcomes, results and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.

**Clinical scenario**
A 20 year old woman presents to the emergency department with shortness of breath and chest pain. Her d-dimer level is abnormal and you have sent her for a ventilation-perfusion scan. The scan result is reported as “low probability for pulmonary embolic disease, however this does not rule out pulmonary embolism”. You have assigned her a low clinical probability of pulmonary embolism score and wonder if this helps interpret the scan.

**Three part question**
In [patients who have undergone ventilation-perfusions scans for possible pulmonary embolus] does [combining clinical probability of pulmonary embolism and ventilation-perfusion scan result] increase the [diagnostic utility]?

**Serum amylase and acute pancreatitis**

Report by John Butler, Consultant

Checked by Damian Bates, Specialist Registrar

**Abstract**
A short cut review was carried out to establish whether a normal serum amylase value rules out the diagnosis of acute pancreatitis. Altogether 191 papers were found using the reported search, of which four presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.

**Clinical scenario**
A 44 year old man presents to the emergency department with a four hour history of severe epigastric pain. You consider a diagnosis of pancreatitis and organise a serum amylase to be taken. You wonder whether a single normal serum amylase result is sufficiently sensitive to rule out pancreatitis in this patient.

**Three part question**
In [patients with abdominal pain] does [a normal serum amylase] exclude [the diagnosis of pancreatitis]?

**Search strategy**

**Search outcome**
Altogether 191 papers found of which four papers were relevant to the original question (table 4).

**Comment(s)**
The gold standard for the diagnosis of pancreatitis is considered to be surgical examination at laparotomy or pancreatic histology. Often in practice such information is either unavailable or obtained at postmortem examination. In the absence of a readily available gold standard it becomes necessary to evaluate serum diagnostic markers against radiological methods such as CT. Only two studies used an independent “gold standard” for all patients to compare the

### Clinical scenario

You are evaluating a 90 kg acutely dyspnoeic diabetic woman in the emergency department. She has a history of left ventricular failure and was an inpatient only two weeks ago with a small myocardial infarction. Her BP is only 90/50 and you feel that she is a high risk patient with poor peripheral venous access who may need high dependency care possibly with inotropes, and you therefore decide that a central line would be of great benefit. Your department has just bought a handheld USS probe and you wonder whether it is worth having a go with this rather than your usual blind landmark technique.

**Report by Joel Dunning, RCS Research Fellow**

**Checked by James Williamson, Clinical Fellow**

**Abstract**

A short cut review was carried out to establish whether ultrasonic guidance reduces the complication rate during central line placement in the emergency department. Altogether 349 papers were found using the reported search, of which two presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.

**Clinical scenario**

You are evaluating a 90 kg acutely dyspnoeic diabetic woman in the emergency department. She has a history of left ventricular failure and was an inpatient only two weeks ago with a small myocardial infarction. Her BP is only 90/50 and you feel that she is a high risk patient with poor peripheral venous access who may need high dependency care possibly with inotropes, and you therefore decide that a central line would be of great benefit. Your department has just bought a handheld USS probe and you wonder whether it is worth having a go with this rather than your usual blind landmark technique.
Three part question
In [patients in the emergency department requiring a central line] is [USS guidance better than blind landmark techniques] at [reducing the complications of insertion]?

Search strategy
Medline 1966-07/03 using the OVID interface. [(exp Ultrasonography/ OR ultrasound.mp) AND (exp Catheterization, Central Venous/ OR central venous catheter.mp OR central line.mp)] LIMIT to human AND English

Search outcome
Altogether 349 papers were found of which two represented the best evidence. This included a meta-analysis and an additional paper. In addition a second meta-analysis not indexed on Medline was identified by cross referencing (table 5).

Comment(s)
Two meta-analyses were identified in this area and only one additional paper could be found that neither meta-analysis included. Both meta-analyses provide strong evidence that USS guided placement significantly reduces complications during catheter placement, number of attempts at insertion and reduction in the number of attempts at insertion for both neck and femoral line insertion. In addition and the NICE meta-analysis provides evidence that insertion time is quicker although this evidence is less convincing. NICE also imply (table 5).

The utility of the tongue blade test for the diagnosis of mandibular fracture

Report by Rashmi Malhotra, Medical Student
Checked by Joel Dunning, RCS Research Fellow

Abstract
A short cut review was carried out to establish whether the tongue blade test is useful in the clinical assessment of patients with mandibular trauma. Altogether 269 papers were found using the reported search, of which two presented the best evidence to answer the clinical question. The author, date and country of publication, patient group

Sensitivity measured in an other study in this hospital and was found to be only 95.5%
Single radiologist to report radiographs—no double reporting
No OPG despite panoramic series known to be more sensitive than mandibular series in detecting mandibular fracture
Single radiologist to report radiographs—no double reporting
No interobserver variability measurements
No CIs calculated
Incorrect use of $t$ test—number too small should have used Fisher’s exact test
No sample size estimates—sample used too small
studied, study type, relevant outcomes, results and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.

**Clinical scenario**
You are evaluating a patient who has attended the emergency department having just been punched on the jaw. He is having difficulty opening his mouth and talking but you can see no step deformity or loose teeth. You recall that while you were on elective you saw the tongue blade test being used routinely in America to select patients for mandibular imaging. For this test the patient is asked to bite on the tongue blade and if the examiner can break the blade while the patient grips it, the patient does not need a mandibular radiograph. You wonder whether this is a sensitive test to use in this patient.

**Three part question**
In [patients with mandibular trauma] is [the tongue blade test] a good diagnostic test for [mandibular fracture]?

**Search strategy**
Medline 1966-7/03 using the OVID interface. [(mandibular fracture.mp.OR exp Mandibular Fractures/) OR {(exp fractures OR fracture$.mp) AND (exp mandible OR mandible$.mp or mandibular.mp)}] AND exp diagnosis OR diagnosis.mp AND maximally sensitive RCT filter LIMIT to human AND English.

**Search outcome**
Altogether 269 papers were found of which two were relevant and are listed in table 6.

**Comment(s)**
No confidence intervals were calculated by Roberts et al for the reported sensitivity of the tongue blade test so we calculated this ourselves: sensitivity 95.4% (CI 84.53% to 99.44%). The confidence intervals are comparatively wide and so the tongue blade test could not stand on its own as a single diagnostic tool in screening for mandibular fractures since missing these fractures can lead to serious long term complications.

The high sensitivities reported by both these studies do suggest, however, that the tongue blade test is a useful screening tool in evaluating patients with mandibular fracture but other clinical predictors must also be considered.

**Clinical bottom line**
The tongue blade test is useful in evaluating patients with possible mandibular fracture.
