Consensus on the prehospital approach to burns patient management

K Allison, K Porter

Burns patients form a large group of trauma patients cared for by first aiders, ambulance staff, nurses, and doctors before reaching specialist care in hospital. Guidance for these important carers is often poor or confused and this engenders anxiety and detracts from optimal patient care. This paper outlines nine key steps in the initial management of burn patients in the prehospital environment based on current available evidence and a consensus of specialists from all disciplines caring for burns patients. The basis of care should be that simple things should always be performed well.

In the United Kingdom, burns patients account for about 175 000 emergency department attendances and 15 000 hospital admissions each year. Consequently the first aid and prehospital care for this large group of patients is of great importance and yet in the authors' experience, simple things are often not done very well.

In 1998 a national survey revealed 58% of UK ambulance services had no specific treatment policy for burns patients. Prehospital carers often feel out of their depth in caring for burns patients, particularly children and there is a lack of teaching and simple, evidence based guidelines.

The Faculty of Pre-hospital Care set out to improve the information available concerning immediate care of the burns patient in simple, unambiguous guidelines, so that any carer (including first aider, ambulance personnel, nurse, or doctor) could administer safe, appropriate care. The process to achieve consensus over these guidelines has taken time and the advice and ratification by all groups that look after burns patients from the point of their injury through to definitive care has been painstakingly followed (table 1 and box 1).

It is hoped that the guidelines although basic, can form the basis for current prehospital care and that they may be updated as new evidence or arrangements for burns patients are made within the UK (box 2).

SAFE APPROACH
For all prehospital emergencies, this acronym can be used to remind the carer as to the first priorities in patient care.

- Shout or call for help
- Assess the scene for dangers to rescuer or patient
- Free from danger
- Evaluate the casualty

STOP THE BURNING PROCESS
The burning process should be stopped/extinguished and the patient should be removed from the burning source. All burnt clothing should be removed (unless it is stuck to the patient) and any jewellery, which may become constrictive. All items of clothing should be brought in a plastic bag to the hospital for examination. For patients with chemical burns, they may need a longer period of irrigation under tap water and specific information about the chemical concerned should be obtained.

COOL THE BURN WOUND
There is often confusion over this process and how long it should last for. It is suggested that the ambulance service despatch system will advise the "999" caller to cool the burn area for up to 10 minutes. Cool running tap water is sufficient and ice cold water should not be used. If cooling has been done before their arrival, prehospital carers should cool for another 10 minutes during package and transfer. If the burn area is small (<5%) then a cold wet towel can be placed on the burn area, on top of the Clingfilm dressing (see next section), but before wrapping up the whole patient to maintain body warmth beneath the blankets. Delays in transporting the burn patient should be minimised, as should the risk of inducing hypothermia, particularly in children. A helpful reminder is to: "Cool the burn wound but warm the patient".

DRESSINGS
Dressings are important to help the patient’s pain control and to keep the burn area clean. The burn area should be covered with a cellophane type wrap Clingfilm, remembering the possible constricting effect of wrapping; smaller pieces are perhaps better than circumferential sheet. The patient should be wrapped up in blankets or a duvet.

In chemical burns after irrigation/cooling, Clingfilm may theoretically worsen the burn effect, so the affected area should be irrigated thoroughly until pain or burning has decreased and only wet dressings should be used. Care should be taken with the management of powder injuries, which may be worsened with water.
available, data regarding the probable chemical should be taken with the patient to hospital.2 32–38

**ASSESSMENT AND MANAGEMENT OF IMMEDIATELY OR IMMINENTLY LIFE THREATENING PROBLEMS: AcBC (Airway with cervical spine stabilisation, Breathing, Circulation)**

It should be remembered that the patient may have other injuries coexistent with their burn injury. These should be suspected, diagnosed, and treated as with any other prehospital emergency. The patient should have high flow oxygen delivered via a non-rebreath mask (15 ls/min). If a patient has an isolated burn injury that is small and when no inhalation injury is suspected the oxygen may not be necessary.20 39 40

**ASSESSMENT OF BURN SEVERITY**

To estimate the size of the patient’s burned area, use the Wallace rule of nines or the “half burnt/half not” approach (serial halves: >1/2, <1/2, 1/4–1/2, <1/4). This latter technique although new, is effective in burn size estimation in prehospital care. Other important features of the burn injury to define are:

- Time of burn injury
- Mechanism of injury (flame (clothes or patient caught fire), flash burn, scald, electrical, chemical)
- Burn within confined space = possible respiratory inhalation injury
- In children and elderly people, always be mindful of potential non-accidental injury.

It is of paramount importance that the prehospital carer keeps good records.41–44

**CANNULATION AND INTRAVENOUS FLUIDS**

The emphasis for patient cannulation should be for the administration of titrated opioid analgesia. It is important that cannulation procedures do not unnecessarily extend the on scene time; this should be limited to two attempts only. Fluid replacement Hartmann’s solution (or 0.9% normal saline if Hartmann’s not available) can be started if the patient is cannulated, but must be started for burns >1/TBSA and/or if time to hospital is more than one hour from time of injury. A guide to fluid volumes is:

- (1000 ml for adult, 500 ml for child 10–15 years, 250 ml 5–10 years, no fluids for under 5s)
- Care should be taken not to over-infuse small, frail, elderly patients with a history of left ventricular failure (LVF)
- Fluid therapy should ideally be warmed.45–48

**ANALGESIA**

As previously indicated, analgesia is best accomplished by cooling and covering the burned area. Intravenous opioid can be titrated to make the adult patient more comfortable and should be accompanied by an antiemetic. In children intranasal diamorphine is an option that may be considered. Entonox should only be used when these options are unavailable as it may be difficult to administer, has varying efficacy, and decreases the oxygen delivery.2 13 36 49–52
TRANSPORT

All treatment should be carried out with the aim of reducing on-scene times and delivering the patient to the appropriate treatment centre. This should be the nearest appropriate accident and emergency department (A&E), unless local protocols allow direct transfer to a burns facility.

Communication with A&E should give the essential information only (age, sex, incident time and mechanism, ABC problems, relevant treatment, ETA).11-12
