Timing of lumbar puncture in suspected subarachnoid haemorrhage

Report by Simon Carley, Consultant
Checked by Magnus Harrison, Specialist Registrar

doi: 10.1136/emj.2004.022038

Abstract
A short cut review was carried out to establish how long after onset of headache a lumbar puncture should be carried out to rule out subarachnoid haemorrhage. Altogether 142 papers were found using the reported search, of which one presented the best evidence to answer the clinical question.

The author, date and country of publication, patient group studied, study type, relevant outcomes, results and study weaknesses of this best paper are tabulated. A clinical bottom line is stated.

Clinical scenario
A 24 year old man presents to the emergency department (ED) with a sudden, severe occipital headache. He collapsed at the time of the initial headache but now feels better. He had computed tomography performed in the ED, which was negative. He was subsequently referred to the medical team who performed a lumbar puncture (LP) one hour after admission (two hours after the initial headache). This was negative and he was permitted home. One week later he represents to the ED by ambulance after another collapse. He is GCS 3 on arrival and dies shortly afterwards. Computed tomography and postmortem examination show the cause of death to be subarachnoid haemorrhage. You wonder if the LP was done too early to spot the original bleed.

Three part question
In [patients with suspected SAH but a negative CT scan] is [late LP (>12 hours) better than early LP] at [definitively diagnosing SAH]?

Search strategy
Medline 1966–10/04 using the Ovid interface. [(exp subarachnoid hemorrhage OR subarachnoid.mp OR subarachnoid haemorrhage.mp) AND (exp cerebrospinal fluid OR spinal fluid.mp OR exp spinal puncture OR lumbar puncture.mp OR xanthochromia.mp) AND (time.mp OR tim$.mp)]] LIMIT to human, English AND abstracts.

Search outcome
Altogether 142 papers were found of which one was relevant to the clinical question (table 1).

Comment(s)
It is common practice to withhold LP until 12 hours after the headache onset. This is based on limited evidence from a small number of papers in this review. Most patients in studies of bilirubin biokinetics had positive CT scans. As LP is normally reserved for those patients with a negative CT scan they are arguably a different group. Despite these limitations current laboratory work suggests that bilirubin will remain undetectable until 12 hours after symptom onset. This should remain the current practice. What is not shown from the literature is that any patient who had negative initial findings (on early LP) followed by positive findings (on late LP). Such cases would provide a convincing argument, but none were found.

CLINICAL BOTTOM LINE
In patients with suspected subarachnoid bleeds, LP is not an adequate rule out strategy until 12 hours after the headache onset.

Best evidence topic reports (BETs) summarise the evidence pertaining to particular clinical questions. They are not systematic reviews, but rather contain the best (highest level) evidence that can be practically obtained by busy practising clinicians. The search strategies used to find the best evidence are reported in detail in order to allow clinicians to update searches whenever necessary. Each BET is based on a clinical scenario and ends with a clinical bottom line that indicates, in the light of the evidence found, what the reporting clinician would do if faced with the same scenario again. The BETs published below were first reported at the Critical Appraisal Journal Club or the Manchester Royal Infirmary or placed on the BestBETs web site. Each BET has been constructed in the four stages that have been described elsewhere. The BETs shown here together with those published previously and those currently under construction can be seen at http://www.bestbets.org. Five BETs are included in this issue of the journal, the last of which is negative.

Timing of lumbar puncture in suspected subarachnoid haemorrhage

Proteolytic enzymes for oesophageal meat impaction

Report by Jason Lee, Specialist Registrar
Checked by Ross Anderson, Senior House Officer
doi: 10.1136/emj.2004.022046

Abstract
A short cut review was carried out to establish whether proteolytic enzymes are effective at resolving oesophageal meat impaction. Altogether 98 papers were found using the reported search, of which three presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.

Clinical scenario
A 35 year old man attends the emergency department with a history of oesophageal obstruction after an attempt at the 20 ounce house-special at the local steak house restaurant. The ENT doctor on-call will be in theatre for some time and you inform the patient you will be seeing the patient in the department. Finding none, you admit the patient but wonder if it would have been effective.

Three part question
In [a patient with oesophageal meat impaction] are [proteolytic enzymes effective] at [inducing resolution and minimising complications]?

Search strategy
Medline 1966–10/04 and Embase 1980–10/04 using the OVID interface. Medline: [(pineapple$.mp OR bromelain.mp OR exp papain OR papain.mp OR trypsin.mp OR chymotrypsin.mp OR enzyme$.mp OR proteolytic.mp OR Adolph’s meat tenderi$.mp OR caroid.mp] AND (exp esophaus$ OR eso$phag$.mp OR esophag$.mp) AND (food.mp OR bolus.mp OR exp foreign bodies OR foreign bod$.mp OR exp meat OR meat.mp OR impact$.mp OR obstruct$.mp OR dystagia.mp OR steak$.mp)] LIMIT to human AND English language. Embase: [pineapple$.mp OR bromelain.mp OR exp papain OR papain.mp OR trypsin.mp OR chymotrypsin.mp OR enzyme$.mp OR proteolytic.mp OR Adolph’s meat tenderi$.mp OR caroid.mp] AND [exp esophagus obstruction OR {(esophag$.mp OR esophag$.mp) AND (food.mp OR bolus.mp OR exp foreign body OR foreign bod$.mp OR exp meat OR meat.mp OR impact$.mp OR obstruct$.mp OR dystagia.mp OR steak$.mp)}] LIMIT to human AND English language.

Search outcome
Altogether 98 papers were found in Medline and 80 in Embase, three of which were relevant to the question posed (table 2).

<td>Aspiration pneumonitis</td>
</tr>
</tbody>
</table>
Comment(s)
Papers evaluating the effectiveness of proteolytic enzymes consist of case reports or case series only. Almost all used sips of a solution containing papain. Published cases up to 1977 report successful passage of the bolus in 89 of 90 cases treated with enzymes but with two fatalities. Since 1977, only two case reports of proteolytic enzyme use for meat oesophageal impaction have been published. One reported haemorrhagic pulmonary oedema (Hall) while the most recent (Maini) reported aspiration pneumonitis from papain use in a patient at a UK hospital in 2000. No reference to pineapple juice use was found in the literature.

► CLINICAL BOTTOM LINE
There is no evidence to support the effectiveness of fresh pineapple juice in resolving meat impaction in the oesophagus. Proteolytic enzymes have been successful but afford an unacceptable risk of serious complications. Their use should be avoided by doctors in the emergency department.

Effervescent agents for oesophageal food bolus impaction

Report by Jason Lee, Specialist Registrar
Checked by Ross Anderson, Senior House Officer
doi: 10.1136/emj.2004.022053

Abstract
A short cut review was carried out to establish whether fizzy drinks alone are effective at resolving food bolus impaction. Altogether 46 papers were found using the reported search, of which six presented the best evidence to answer the clinical question. The author, date and country of publication, patient group studied, study type, relevant outcomes, results and study weaknesses of these best papers are tabulated. A clinical bottom line is stated

Clinical scenario
It is Christmas day when a 70 year old woman is brought to the emergency department by her family with a history of oesophageal obstruction after eating her turkey dinner. You wonder if a fizzy drink might resolve the obstruction.
Three part question
In a patient with food bolus impaction are effervescent agents effective at inducing resolution and minimising complications?

Search strategy
Medline 1966-10/04 and Embase 1966-10/04 using the Ovid interface. Medline: [effervescent.mp OR fizzy.mp OR exp carbonated beverages OR coke.mp OR cola.mp OR coca-cola.mp OR soda.mp OR sodium bicarbonate.mp OR exp sodium bicarbonate OR exp citric acid OR citrate.mp OR citric acid.mp OR tartaric acid.mp OR carbex.mp OR gas-forming.mp] AND [exp Esophageal Sienosis OR {(oesophag.mp OR esophag$.mp) AND (food.mp OR bolus.mp OR exp foreign bodies OR foreign bodb.mp OR mcat.mp OR impact$mp OR obstruct$.mp OR dysphagia.mp OR steak$.mp)}] LIMIT to human AND English language. Embase: [effervescent.mp OR fizzy.mp OR exp carbonated beverages OR coke.mp OR cola.mp OR coca-cola.mp OR sodium bicarbonate.mp OR citrate.mp OR exp citric acid OR citric acid.mp OR exp tartaric acid OR tartaric acid.mp OR exp carbex OR carbex.mp OR gas-forming.mp] AND [exp esophagus obstruction OR {(oesophag.mp OR esophag$.mp) AND (food.mp OR bolus.mp OR exp foreign body OR foreign bodb.mp OR mcat.mp OR impact$mp OR obstruct$.mp OR dysphagia.mp OR steak$.mp)}] LIMIT to human AND English language.

Search outcome
Altogether 35 papers were found in Medline and 46 papers in Embase. After exclusion of papers using a combination of glucagon or buscopan with effervescent agents, six papers remained that were relevant to the question posed (table 3).

Comment(s)
Effervescent agents have successfully resolved oesophageal food impaction in a number of cases. However, these studies represent only low level of evidence (case reports, case series, or case-control studies) and in most studies the patients had undergone prior barium swallow to conclude the diagnosis. It is feasible that these cases resolved through the “weight of column effect” of the barium. A wealth of correspondence exists in journals from clinicians stating that they have used effervescent agents “many times” safely and successfully. They do not, however, provide data. Overall, the published success rate of effervescent agents is 80% (52 of 65 cases). The complication rate, 3% (2 of 65 cases), is low but exceeds the figures quoted in the literature for endoscopic removal. More research is needed in this area.

▶ CLINICAL BOTTOM LINE
Effervescent agents seem to be effective at resolving oesophageal food obstruction but their use is not without risk of complications. Consultation with ENT before their use is recommended.

Humeral fractures and non-accidental injury in children

Report by Robert Williams, Specialist Registrar
Checked by N Hardcastle, Senior House Officer
doi: 10.1136/emj.2004.022061

</tbody>
</table>
publication, patient group studied, study type, relevant outcomes, results and study weaknesses of these best papers are tabulated. A clinical bottom line is stated.

Clinical scenario
A 22 month old child attends the department and is reported not to be using her arm. You question the mother of the child who explains the child seems to have injured herself at nursery, although no one can corroborate the story. Radiography shows an undisplaced humeral fracture. Further inquiry is unrewarding, and you wonder whether the presence of the fracture alone is sufficient to support a diagnosis of non-accidental injury.

Three part question
In [children in whom non-accidental injury is suspected] what [is the specificity of] an [isolated proximal humeral fracture]?

Search strategy
Medline 1969–10/04 using the OVID interface. [Exp battered child syndrome OR battered child syndrome.mp OR exp child abuse OR non-accidental injury.mp OR NAI.mp] AND [exp humeral fractures OR {(exp fractures OR fracture$.mp OR exp fractures, closed OR exp fractures, open) AND (exp humerus OR humer$.mp)}].

Search outcome
Altogether 44 papers were found of which 42 did not address the question directly. The remaining two papers are shown in table 4.

Comment(s)
The detection and diagnosis of child abuse is difficult and requires a holistic approach. However, traditional teaching has suggested that certain injuries are pathognomic of abuse. These papers attempt to define the specificity for child abuse of various types of humeral fracture. However, both studies lack an adequate “gold standard” that abuse was the cause. It is possible that abused children may have been missed and also the converse could be true. Despite this, the reported incidence of abuse associated with these fractures seems high. In particular spiral or oblique fractures, in children under the age of 3 more often occur as a result of abuse.

► CLINICAL BOTTOM LINE
Although not pathognomonic of child abuse, the presence of a humeral fracture in a young child should lead to further investigation of its cause.

Strait RT, Siegel RM, Shapiro RA. Humeral fractures without obvious etiologies in children less than 3 years of age: when is it abuse? Paediatrics 1995;96:677–71.

Torn frenulum and non-accidental injury in children

Report by Stewart Teece, Clinical Research Fellow
Checked by Ian Crawford, Senior Clinical Fellow
doi: 10.1136/emj.2004.022079

Abstract
A short cut review was carried out to establish whether a torn frenulum in a child is indicative of non-accidental injury. Altogether 104 papers were found using the reported search, of which none presented any evidence to answer the clinical question. It is concluded that there is no evidence available to answer this question. Further research is needed.

Clinical scenario
A 2 year old boy is brought to the department with bleeding from a mouth injury. His father states that he fell over pushing his dummy into his mouth. The child has no other obvious injury and although the mechanism of injury sounds plausible you find a torn frenulum on examining his mouth. Remembering this as an indicator of non-accidental injury you wonder whether this injury alone is sensitive/specific enough to support this diagnosis.

Three part question
In [a child] with [a torn frenulum] what [is the sensitivity and specificity of this sign as an indicator of non-accidental injury]?

Search strategy

Search outcome
Altogether 104 papers found none of which answer the three part question.

► CLINICAL BOTTOM LINE
There seems to be no evidence for the sensitivity/specificity of torn frenulum in the investigation of non-accidental injury.
