ABSTRACT

The UK is currently in the process of implementing a modified response to chemical, biological, radiological and nuclear and hazardous material incidents that combines an initial operational response with a revision of the existing specialist operational response for ambulant casualties. The process is based on scientific evidence and focuses on the needs of casualties rather than the availability of specialist resources such as personal protective equipment, detection and monitoring instruments and bespoke showering (mass casualty decontamination) facilities. Two main features of the revised process are: (1) the introduction of an emergency disrobe and dry decontamination step prior to the arrival of specialist resources and (2) a revised protocol for mass casualty (wet) decontamination that has the potential to double the throughput of casualties and improve the removal of contaminants from the skin surface. Optimised methods for performing dry and wet decontamination are presented that may be of relevance to hospitals, as well as first responders at the scene of a chemical incident.

INTRODUCTION

The deliberate use of toxic materials represents a serious threat to society. In particular, chemical warfare agents are indiscriminate weapons that can have a devastating impact when used on unprotected civilian populations, as recently evidenced in Syria.¹ Any complacency based on the notion that chemical warfare agents are limited to politically unstable regions was recently dispelled by the use of a 'novichok' nerve agent in the UK.^{2,3} The current threat level for international terrorism in the UK is presently classed as 'severe'.⁴

Exposure of individuals to liquid or particulate substances presents a particular challenge to the emergency services, as casualties will need to undergo immediate disrobe and decontamination in order to mitigate the risk of adverse health effects. Such materials include chemical warfare agents (e.g. VX, soman and sulphur mustard)⁵ and toxic industrial chemicals.⁶

The UK approach for preparing and responding to the threat of terrorism has been developed over the last 15 years as part of the UK Government's 'CONTEST' strategy.⁷ One outcome of this strategy was the development of the 'Model Response', which sets out the operational parameters for responding

to the deliberate release of chemical, biological or radiological materials.⁸ Along with a corresponding investment in equipment and training, the Model Response has provided the UK's emergency services with a range of bespoke resources and procedures for effectively dealing with chemical, biological, radiological and nuclear (CBRN) and hazardous material (HazMat) incidents.

The model response begins with the recognition that an incident has occurred as part of the STEP 1-2-3+ process (table 1).⁹

The first stage of the CBRN response is to report back to the control room and provide a situation report based on the METHANE mnemonic: Major incident declared, Exact location, Type of incident, Hazards, Access/egress, Number of casualties, Emergency service(s) required. Under the original Model Response, first responders would subsequently withdraw to a safe distance and await deployment of trained responders with appropriate protection and detection capability, medical countermeasures and bespoke disrobe and decontamination facilities. Clearly, the clinical benefit of such an approach would be dependent on the timely arrival of assets on-scene. For incidents involving the release of biological or radiological materials, a short delay in the deployment of specialist resources may not have significant health consequences for exposed individuals. However, this may not be the case for chemical agents, particularly those with a rapid onset of action, such as hydrogen cyanide or nerve agents.¹⁰ For this reason, a series of research projects were commissioned from 2008 to evaluate various aspects of the Model Response.¹¹⁻¹³ These primarily focused on issues relating to the rapidity of the response and optimisation of the existing mass casualty disrobe and decontamination process. The initial research trials were performed as part of a programme of work known as Optimisation through Research of Chemical Incident Decontamination Systems ('ORCHIDS') led by the UK Health Protection Agency (now Public Health England) and its partners. The outcome of the ORCHIDS projects led to a number of recommendations on how the Model Response could be optimised to improve casualty management and has led to the implementation of a revised process that entails an initial and specialist (or strategic) operational response (IOR and SOR, respectively; figure 1).⁹ Subsequent work has confirmed the effectiveness of

Step 1	One incapacitated casualty with no obvious reason: approach as normal.
Step 2	Two incapacitated casualties with no obvious reason: approach as normal but with caution.
Step 3 plus	Three or more casualties incapacitated in close proximity for no obvious reason: instigate CBRN response actions.

this approach and has extended the scope of evidence to include hair decontamination.^{14 15}

EVIDENCE BASE

The IOR and SOR build on scientific evidence derived from a series of in vitro, in vivo and human volunteer studies (figure 2). Initial (in vitro) skin absorption studies focused on the effects of individual decontamination parameters, such as the duration of decontamination and the protective effects of normal (civilian) clothing against chemical warfare agents, toxic industrial chemicals and simulants.¹³ The outputs of the in vitro studies included

a putatively optimised mass casualty decontamination (MCD) protocol and information on the temporal effects of disrobing and decontamination. The combined outputs of the in vitro study were subsequently confirmed in a series of in vivo (animal) studies¹³ prior to a final series of human volunteer studies¹³ using two relatively non-toxic simulants: fluorescent particles to model a biological or radiological agent¹⁶ and methylsalicylate, previously used as a simulant for chemical warfare agents.^{17 18} Collectively, these studies resulted in a number of evidence-based recommendations, including: (1) the need to introduce an 'emergency disrobe and decontamination' stage prior to the arrival of bespoke MCD units and (2) the optimisation of MCD through adoption of the 'ORCHIDS Protocol', namely a shower duration of 90 s with water at a temperature of 35°C and a washing aid such as a face cloth.¹⁶ Overall, the ORCHIDS projects indicated that, while the effectiveness of MCD can be substantially improved by relatively simple and cheap interventions, there is a need to improve the rapidity of the response to make it more patient oriented and to maximise the use of time during the earliest phases of an incident, hence the introduction of the IOR. This approach has since been adopted in the UK¹⁹ and within US Federal Guidance.¹⁴

Figure 1 Outline of ORCHIDS projects illustrating a three-tier approach based on in vitro, in vivo and human volunteer studies. CWAs, chemical warfare agents; TICs, toxic industrial chemicals. Simulants were fluorescent particles and methylsalicylate.

Figure 2 Salient features of the original Model Response in comparison with the new IOR. The IOR, which is essentially a form of first aid, leads into the SOR, where additional resources are made available, such as mass decontamination units (MDU).

The introduction of an early ‘emergency disrobe and decontamination’ stage requires the use of dry, absorbent materials for decontamination that may be more readily available at the scene of an incident than warm, soapy water. Moreover, there is a growing recognition that dry decontamination may offer other advantages over aqueous (shower based) decontamination. For example, dry decontamination does not lead to the generation of large volumes of contaminated waste, does not cause transfer and spreading of contaminants through clothing and is not associated with the ‘wash-in’ or ‘rinse-in’ effect, where the dermal absorption of certain chemicals may be significantly enhanced by washing with water.^{20–23}

Recent work has demonstrated that a variety of absorbent materials particularly those that are readily available in a clinical environment (such as an ambulance or hospital) could be used for emergency decontamination.^{24–25} Such materials include absorbent tissue paper, incontinence pads and absorbent wound dressings, as well as domestic products such as cotton wool, kitchen paper, nappies (diapers) and toilet paper. Above all, the ad hoc nature of disrobe and dry decontamination means that the process can be instigated within seconds or minutes of exposure. This is a critical feature, since the effectiveness of disrobe and decontamination decreases rapidly with time.^{10–26} It should be noted that the emergency disrobe and dry decontamination element of the IOR is specific to non-corrosive, liquid contaminants. The efficacy of dry decontamination is substantially reduced if the contaminant is a solid, such as a powder.²⁴ Moreover, the cooling effects of water may be more appropriate for treating skin contamination with corrosive chemicals, although dry decontamination may be of clinical benefit in reducing exposure until a source of water becomes available.

COMPARISON OF IOR/SOR AND MODEL RESPONSE

The main feature of the new response process is the introduction of an ‘emergency disrobe and decontamination’ stage at the earliest possible opportunity (figure 2). This new step allows the instigation of these potentially life-saving processes to be performed as soon as readily practicable rather than after the arrival of specialist resources. A second major improvement is the utilisation of the ‘ORCHIDS’ showering protocol, which may halve the time taken to process casualties through mass decontamination units (MDUs).

The addition of an emergency disrobe and decontamination step necessitates a joint dynamic hazard assessment (JDHA)

to ensure the safety of emergency responders when issuing verbal instructions at the scene of the incident⁹. The JDHA is performed by senior members of the emergency services prior to implementing the emergency disrobe and decontamination process. The IOR includes an emphasis on the importance of effective communication for the success of emergency disrobe and decontamination. Responders should seek to foster public trust and confidence by communicating what they know about the incident, why and how casualties need to be disrobed and decontaminated, providing demonstrations of disrobe and decontamination when practical and encouraging mutual assistance. These communication strategies are likely to improve the efficiency and experience of undergoing disrobe and decontamination for affected casualties.²⁷

GUIDANCE ASSUMPTIONS AND LIMITATIONS

The following guidance makes the assumption that established procedures for identifying and responding to a chemical incident have been implemented. For example, the ‘STEP 1-2-3 PLUS’ protocol for determining the appropriate response and the ‘METHANE’ situation report for communicating information back to control centres.⁹ It is imperative that emergency responders maintain an awareness of the situation and do not put their own safety at risk. It is also important to note that the following protocols relate to casualties who are able to understand and perform instructions: guidelines for non-ambulant casualties are currently under development. The IOR guidance reported here is specifically for dealing with non-corrosive, liquid chemical contamination and not powders or biological/radiological contamination. However, in circumstances where the nature of the contaminant may not be readily apparent, flexibility and/or adaptation of procedures may be necessary.

THE IOR DISROBE AND DRY DECONTAMINATION PROTOCOL

The mnemonic ‘EMERGENCY’ may provide an *aide-mémoire* for the disrobe and dry decontamination protocol (table 2).

The salient features of the disrobe and dry decontamination process are available in video format produced by the National Ambulance Resilience Unit and NHS England.²⁸ A pictogram demonstrating the dry decontamination process for casualties with scalp hair is presented in figure 3. The dry decontamination stage can be repeated (subject to availability of absorbent material) until MDUs become available. This will help to

Table 2 The EMERGENCY mnemonic for key elements of the Initial Operational Response

E	Evacuate: casualties should be instructed to leave the contaminated area if they have not already done so.
M	Move the casualties as a group to a safe distance, away from any potential source of contaminant. Ideally, this should be uphill and upwind and preferably in a sheltered (external) area away from strong winds and rain.
E	Engage with casualties to explain what is happening and how they can help themselves by following your instructions and advice. Some casualties may not wish to cooperate for cultural, religious or other reasons: focus initial attention on compliant individuals.
R	Remove as much clothing as possible. It is important to communicate the benefits of rapid disrobe to the casualties in order to gain their cooperation. The more clothes that are removed the better, but be mindful of modesty concerns. Where possible, do not remove clothing over the head. If available, trauma scissors can be used to cut away clothing.
G	Give any available absorbent material to the casualties. Ideal materials include 'blue roll' (absorbent paper tissue), wound dressings, incontinence pads, cotton wool, toilet paper and paper towels. Do not get close to casualties when handing out the decontamination material.
E	Establish dry decontamination. Using a blot and rub motion, start with the face, then the hands, then any other exposed skin areas and finally the hair. If availability of material permits, ask casualties to use clean swatches of absorbent material for each body area. Above all, ensure that casualties do not reuse material after decontaminating their hair. Encourage casualties to repeat the entire process several times, paying particular attention to the hair, face and hands.
N	Note the development of any signs and symptoms. Begin triage to identify priority casualties.
C	Communicate constantly with casualties to encourage cooperation and reassurance that disrobe and decontamination will remove the vast proportion of any contamination. Confirm to the casualties that advanced medical assistance is on its way.
Y	Yards not inches: maintain a safe distance from casualties at all times, but close enough so that they can hear instructions.

engage and focus casualties and will further improve decontamination effectiveness.

THE SOR DISROBE AND WET DECONTAMINATION ('ORCHIDS') PROTOCOL

The 'ORCHIDS protocol' is designed for use in MDUs that may be deployed by the fire and rescue service at the scene of an incident or available at designated NHS hospital EDs. Such units generally comprise a three-chamber tent (disrobe, shower and re-robe areas), a boiler pump (to deliver warm shower water), sump pumps (to remove waste water from within the MDU) and may also include warm air blowers (for heating), bund tanks (to collect waste effluent) and the provision of 're-robe' packs.^{10 29} It is important to note that MDUs do not normally incorporate air handling units and so adequate steps to maintain good ventilation should be taken to prevent the accumulation of gas, vapours and aerosols during and after use by casualties. Prior (emergency) decontamination will reduce the accumulation of vapour within decontamination units.¹⁴ It is essential that MDUs and designated operators are regularly exercised to maintain a state of readiness. The ORCHIDS protocol is twice as fast as the previous (Model Response) method but at least as effective.³⁰

In the case of exposure to non-caustic liquid contaminants, casualties should undergo disrobe and dry decontamination before proceeding to wet decontamination. This will reduce or eliminate the risk associated with the wash-in effect, where the dermal absorption of certain chemicals may be significantly

Figure 3 Pictogram demonstrating the blot and rub method for performing dry decontamination. Following disrobe [1], use a 'blot then rub' technique to apply the decontamination material. [2] Ideally, clean decontamination material should be used for each step (subject to availability). Clean the top and sides of the head first [3], with head tilted back. Next, decontaminate the face [4]. The hands should be cleaned next [5], followed by any other skin areas that may not have been initially protected by clothing [6]. Repeat steps 3–6 as necessary. Use clean decontamination material for each step (if available in sufficient quantity). Used decontamination material should be placed by the casualties into a suitable waste receptacle (eg, clinical waste bag and bin liner, etc.) immediately after use.

Table 3 The WASHED mnemonic for the ORCHIDS mass casualty (wet) decontamination protocol

W	Warm water: the shower water temperature should be at least 35°C (but lower than 40°C) to ensure optimal removal of contaminants.
A	Aid: the removal of a chemical contaminant (particularly powders) can be increased by 20% by the use of a washing aid such as a cotton face cloth or sponge during showering. Washing aids should be safely disposed of after single use. Do not reuse washing aids.
S	Soap: the use of detergent at a concentration of 0.1%–0.5% (v/v) has been shown to assist decontamination of lipophilic (oily) substances. Most UK mass decontamination units (MDUs) have the capacity to add liquid detergent to the shower water via a metered dosing system.
H	Head to toe: casualties should be instructed to start by washing their head and to work their way down to their feet. Casualties should tilt their head backwards when washing their hair to avoid spreading contamination to the face.
E	Expedited: in order to avoid the 'wash-in' effect (which may enhance the dermal absorption of certain chemicals), the shower needs to be performed within 90 s. Ideally, 1 min with soapy water and the remaining half minute using water only (rinse). The 90 s timing reflects the optimal shower duration. Longer durations should be avoided.
D	Drying with a towel is the critical step for removing many chemical contaminants! Following use, towels must be considered to be heavily contaminated and should be disposed of according to local regulations.

enhanced by the presence of water, particularly organophosphorus compounds³¹ and sulfur mustard.³²

Following disrobing (if casualties are still clothed), the ORCHIDS showering protocol follows the 'WASHED' mnemonic (table 3).

A final consideration is the finite capacity for rerobing within MDUs. Use of the shorter ORCHIDS protocol may cause a 'bottleneck',³³ so plans should be in place to provide additional areas for casualties to rerobe.

DRY OR WET DECONTAMINATION?

To reiterate, dry decontamination of liquid chemicals is at least as effective and is generally safer than wet decontamination. Therefore, dry decontamination should be the default incident response option. However, there are certain circumstances where wet decontamination may be preferable. A decision flow-chart (eg, figure 4) can be used to determine the most appropriate course of action. It can be readily ascertained from the flow chart that any non-corrosive liquid contaminant (such as sulfur mustard, all nerve agents or solutions containing pesticides or cyanides and so on) should be treated by dry decontamination. The use of any form of wet decontamination (including the standard NHS 'rinse-wipe-rinse' method) for such materials

Figure 4 Basic flow chart for determining the appropriate response for managing contaminated casualties.

is contraindicated due to the potential for enhanced dermal absorption. In contrast, solid forms of toxic, radioactive or biological contaminants should be subject to wet (SOR) decontamination. The only scenario that does not follow this simple binary decision process is exposure to corrosive liquids (eg, strong acids or oxidising agents), where disrobe and immediate flushing of affected areas with any available source of water is an urgent requirement. However, if water is not immediately available, disrobing and dry decontamination should be performed as an interim measure to reduce dermal exposure prior to the availability of water.

Hair contamination

Lipophilic (oil soluble) contaminants may rapidly penetrate hair fibres. This can limit the effectiveness of decontamination and form a reservoir for subsequent evaporation ('off-gassing').¹⁴ In such instances, removal of contaminated hair should be considered to ensure the safety of casualties and medical staff.

Casualty compliance

The effectiveness of the IOR and SOR processes will be largely dependent on the level of casualty compliance. Correspondingly, rapid instigation of good communication between first responders and casualties will be a key factor.^{34 35} Key points to convey to casualties include information about the incident, what actions are being taken to assist casualties and the provision of clear instructions for the disrobe and decontamination procedures, including the expected health benefits.^{9 36 37} It has been recommended that non-cooperative casualties be made aware of the potential adverse health effects of non-compliance.³⁶

Decontamination of Non-ambulant casualties

The new IOR and SOR processes described above have been developed specifically for ambulant casualties, that is, individuals who can both understand instructions and perform self-decontamination with minimal assistance. Whilst some progress has been made in developing non-ambulant decontamination protocols³⁸, further work is required to develop optimised communication and methods for this population of casualties.^{14 15}

SUMMARY

The UK is in the process of implementing a modified response to CBRN and HazMat incidents that introduces an IOR to complement the SOR. The IOR provides a capability for the rapid disrobe and emergency decontamination of chemically contaminated casualties and thus provides an early, practical and effective clinical intervention while the arrival of specialist resources is awaited. For all incidents involving exposure to non-corrosive liquid contaminants, dry decontamination is the default response protocol.
